

ABSTRACT OF THE DISCLOSURE

The box has a rear wall which is composed of two vertically spaced segments. The upper segment is foldable from a vertical position to a horizontal position. An interior wall is foldably connected to the upper segment. The interior wall together with the upper segment, when horizontal, defines a partition which separates the interior of the box into lower and upper compartments. The rear wall of a second embodiment of the box is unfolded but the interior wall which is connected to it has a pair of spaced folds which define inner, intermediate and outer segments. The interior wall folds into lower and upper alternative positions. In lower position, the intermediate and outer segments are generally horizontal and are spaced apart from both the lower wall of the box and its closed lid. In the upper position the inner and intermediate segments are generally horizontal and are at generally the same level as the upper edges of the side walls of the box.
